Mailbox Move In Exchange 2010...

As I was playing with the Exchange 2010 Console, the "Move Request" section under Recipient caught my attention. But, there was no option other than to export the list. So, I decided to run a move and see what happens. Two types of mailbox move is supported in 2010.

- Local Move - Moving a mailbox from one database to another on the same or different server. If the servers are in the same exchange organization.
- Remote Move - Moving a mailbox to a database in a different forest.

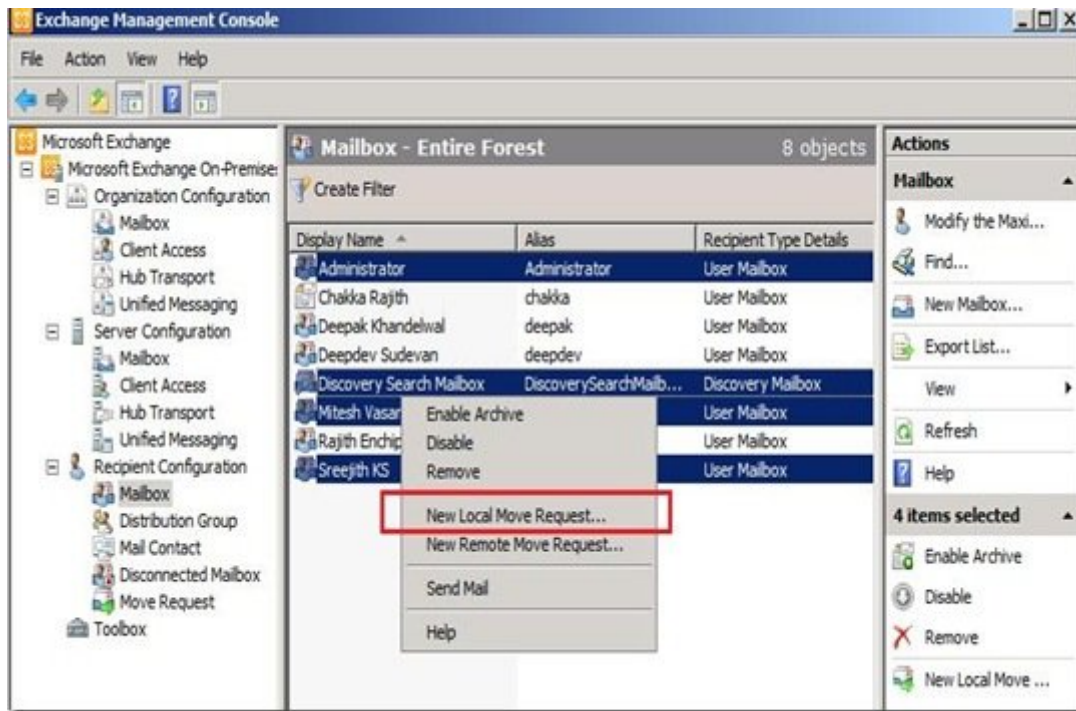

More Info Added:

Mailbox move in 2010 is asynchronous and hence users can still access data while the mailbox is being moved. The actual move is performed by a new service in 2010 named "Exchange Mailbox Replication" (EMR). This service runs on a CAS server and that indicates that the CAS servers are responsible for the mailbox move.

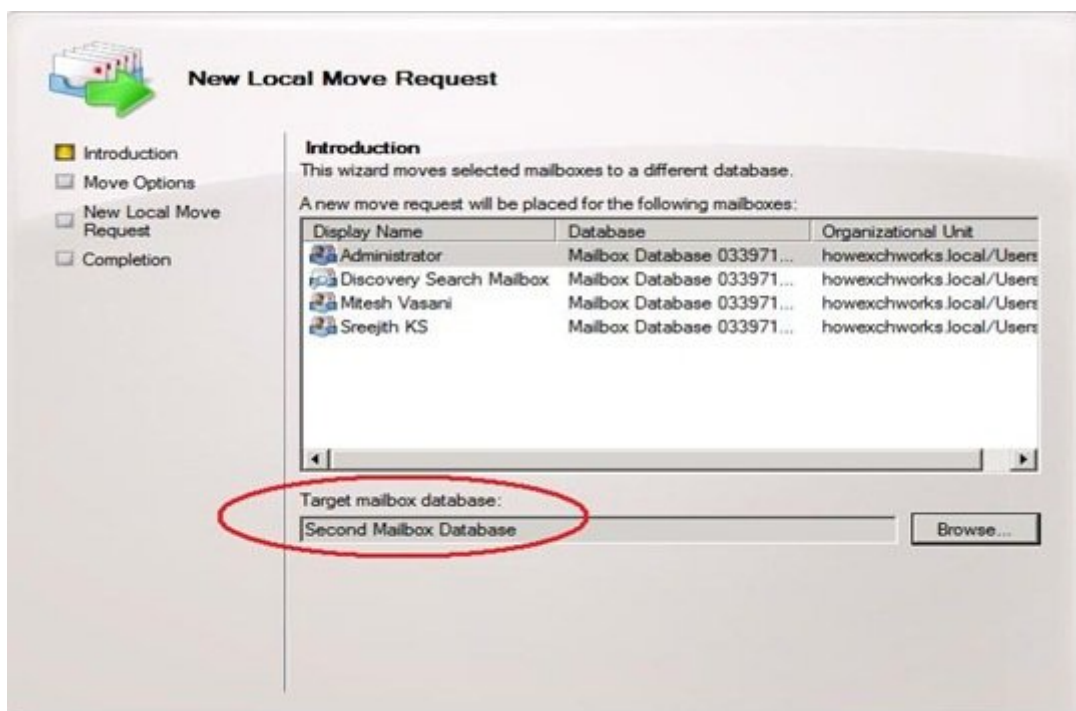

The mailbox's dumpster is moved, as long as both source and destination servers are 2010. The mailbox move history is maintained in the mailbox.

Mailbox move from Exchange 2000 and 2007 SP1 to 2010 is not supported.

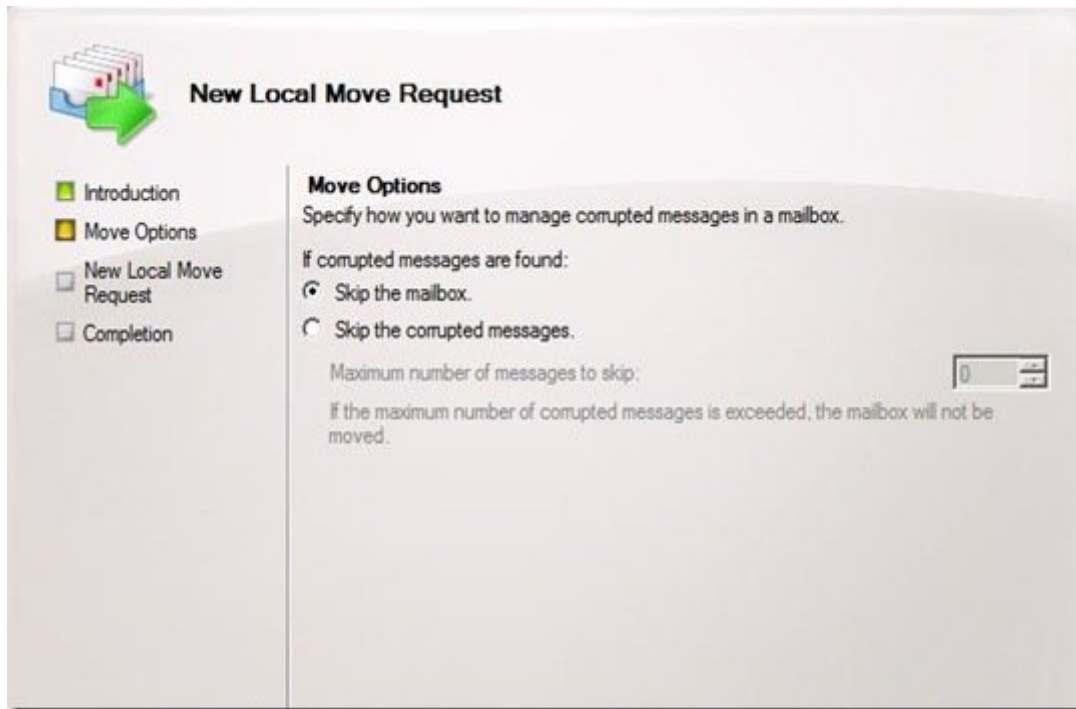

In order to move a mailbox from one database to another within the same organization, launch the Exchange 2010 Console and navigate to Recipient Configuration -> Mailboxes. Right click the mailbox in question and select "Move Request".

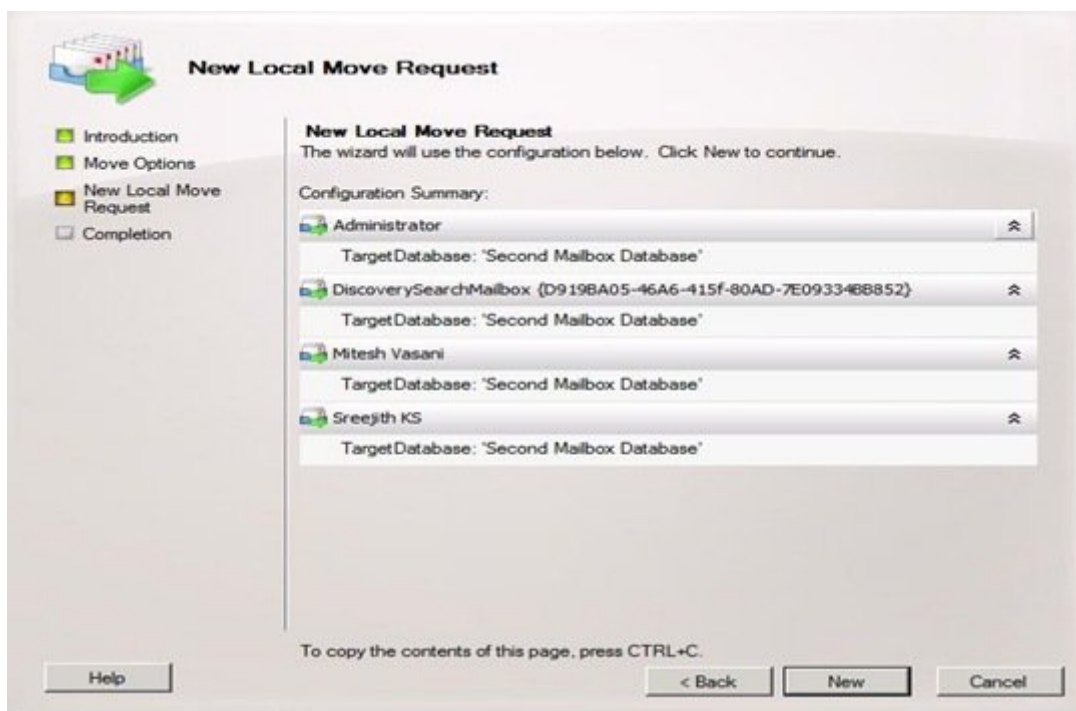

Select the target database for the mailbox.

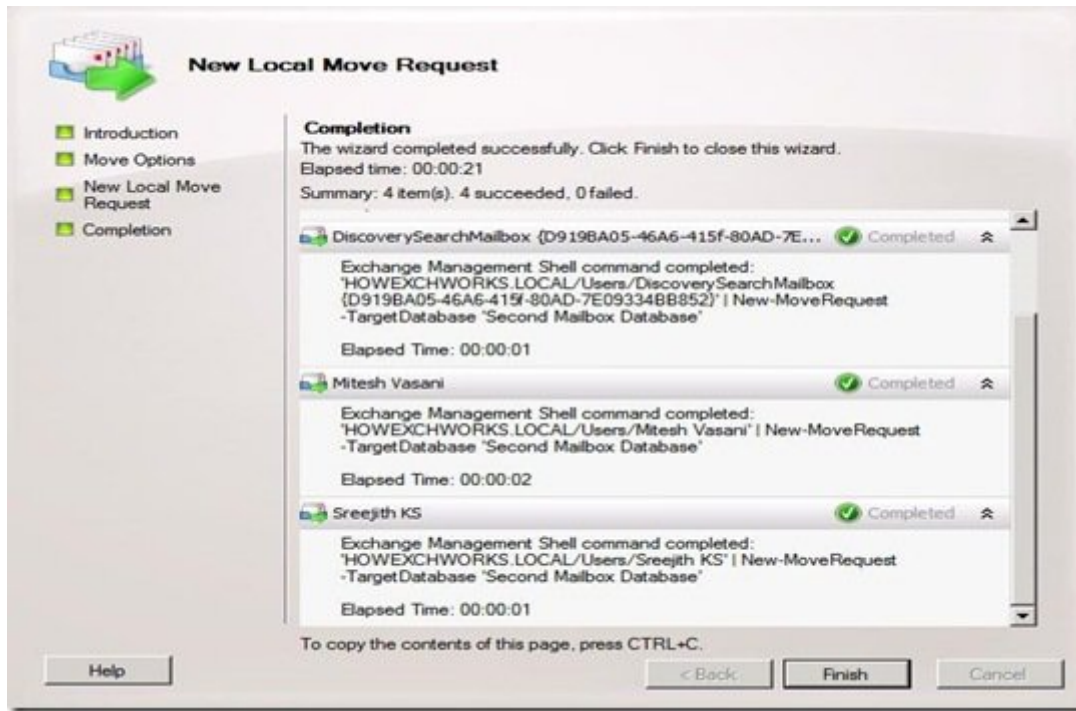

Select your move option – whether to skip the mailbox move if corrupted messages are found or not, skip corrupted messages & go ahead.

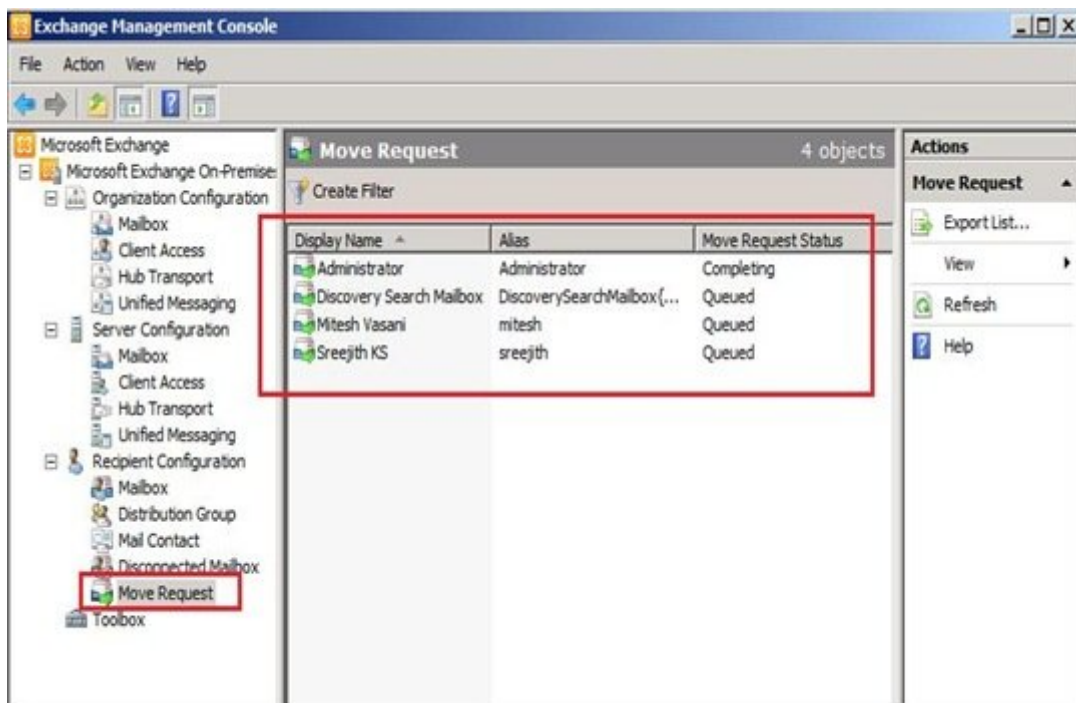

A summary of the mailboxes that are moved is displayed. Click New to continue.

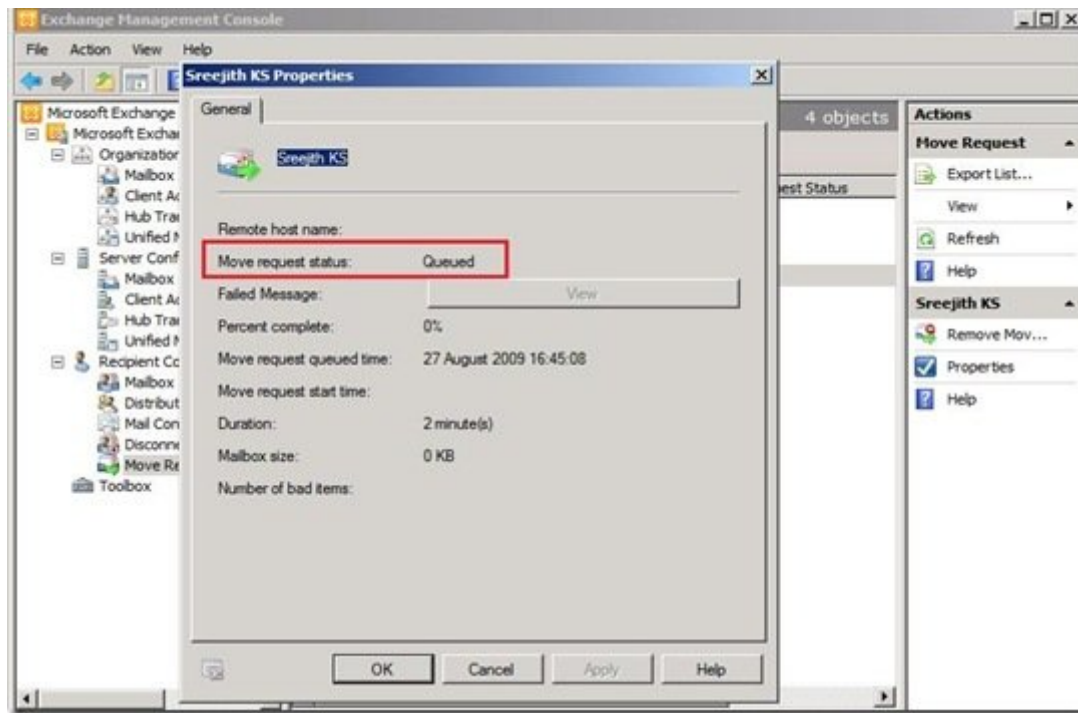

The wizard checks and initiates the mailbox move by submitting a mailbox move request. Take the cmdlet & you will find out that the cmdlet run is [New-MoveRequest](#) and not Move-Mailbox. complete your mailbox move request.

Exchange hasn't finished moving the mailboxes, but has only received a request to move. In order to check the status of the mailbox move, we need to go to the "Move Request" section. The list of mailboxes moved along with the status is displayed. You can use [Get-MoveRequest](#) cmdlet to get the status of mailbox move if you prefer to use the shell.

You can double click on any mailbox to get more information.

In short, mailbox move process has been slightly changed in Exchange 2010. The admin submits the request to the server and the actual move is run in the background & hence it would appear that the move wizards have completed pretty quickly even for large mailboxes. The reason being the process runs in the background, whereas in Exchange 2007 the wizard actually runs through the entire process. Once the wizard finishes, all the mailboxes will be in the target database.

To move a mailbox using the shell, run the command

`New-MoveRequest -identity username -TargetDatabase "database name"`

Once the mailbox move is initialized, you can check the status by running

`Get-MoveRequest -identity username`

Intresting.. So can we schedule the move as we could do we Move-Cmdlet in Exch 2007 seems to have any scheduling in new-MoveRequest. There a switch for suspend in New- but no way to specify time or date. There is Resume-Moverequest commandlet to resum we may have to resume using windows scheduler or something.

Rajith- Do Powershell have any command to do schdeduling if so then we could pipe res MoveRequest command to it and get a combine funtion.

Good stuff keep it up

Deepak, I have added more info in the article. You can run a move request with -suspen and later on resume it when you want to. But, as mailbox moves are asynchronous & on move it anytime you want, as long as the server can handle it.

New-MoveRequest rajith -TargetDatabase "Second Database" -suspend

Get-MoveRequest rajith | Resume-MoveRequest.

A quick look at the cmdlet doesn't bring any date/time scheduling option. I will update the across one.

Rajith

I found this

[http://technet.microsoft.com/en-us/library/dd876878\(EXCHG.140\).aspx](http://technet.microsoft.com/en-us/library/dd876878(EXCHG.140).aspx)

```
.\MoveMailbox.ps1 -Identity "Tony@Contoso.com" -TargetDatabase "DB2"
```

which allow you to move synchronously similar to Move-Mailbox cmdlet.. but still missing option but it has additional -startBatchsize option to give batch size.

If you are moving a mailbox from an Exchange 2003 database, the mailbox move will be

Create a move request that suspends before completion

This example creates a move request that is suspended after all the initial content is moved. The mailbox is locked down and switched over to the new location.

```
New-MoveRequest -Identity 'tony@alpineskihouse.com' -TargetDatabase DB01 -SuspendWhenReadyToComplete
```

This command could be useful if we wanted all the mailboxes in one location to move to the same time or prepare the destination and keep it ready for switch over with very little downtime.

I don't think this will work for Exchange 2003 mailboxes since they are taken offline while the move is suspended. I'm not sure if they become online when move is suspended.

Can I move mailbox from Exchange 2007 SP2 ? How would I do that? I have had a hard time finding the right cmdlet for this operation.

29 SEPTEMBER 2009 13:25

Rajith Jose Enchiparambil said...

ComplexxL9, you can only move from Exchange 2007 SP2 to 2010. 2007 SP1 won't work with the move-mailbox cmdlet either. Use 2010 EMC or New-MoveRequest cmdlet.

Hi,

I try to move one user from Exch2010 back to sbs2003 for testing purposes - but I don't know if there are any tips?

Same here when moving back mailbox from 2010 to 2003: I'm unable to specify targetdatabase. I was able to find syntax for targetdatabase in this command:

```
Get-MailboxStatistics -identity testusr -includemovereport | format-list
```

but I'm still receiving error for new-moverequest that mailbox database does not exist

To move a mailbox from 2010 back to 2003 you need to find the DN of the 2003 mailbox; you can do it like this:

```
$temp = get-mailbox
```

```
$dn = $temp.database.distinguishedname
```

Then move your mailbox like this:

```
new-moverequest -targetdatabase $dn
```
